Algorithmic Game Theory

Notes by Arjun Maneesh Agarwal

based on course by Prajakta Nimbhorkar

- 1. Games and Equilibria: We are assuming games where everyone is acting selfishly. When everyone doesn't wish to switch strategies, we get an equilibrium.
 - We will see two-player games and multiplayer games.
 - Equilibrium and existence and computation.
- 2. Mechanism Design: Given multiple selfish agents, we need to make a mechanism that encourages (or discourages using hardness) the behavior we wish to encourage.
 - We will see auctions, voting etc.
- 3. Fair Division: This is an allocation problem where we want to allocate some resources in a 'fair' (or less unfair) way.
 - Distributing divisible and indivisible resources fairly among agents, given valuation.
 - EF, EQ, PROP and its relaxations.

Table of Contents 2.5. Existence of Nash Equilibrium (mixed) in finite strategic form games . 14

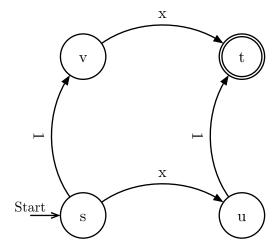

1. Games and Equilibria

We make the following assumptions:

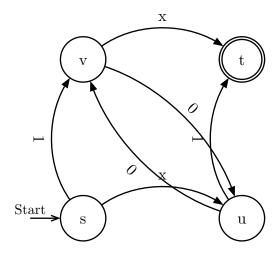

- 1. Rationality/selfishness: Each agent attempts to maximize own payoff and believes others will do so as well as well has knowledge of same behavior being
- 2. Intelligence: Agents have enough computational resources to take into account the strategies and behaviors of others.
- 3. Common Knowledge: P, S_i, μ are known to everyone and everyone knows that everyone knows them and so on.

1.1. Braess's Paradox

Taking the example of traffic, let the network be:

In this case, the equilibrium is 1.5 hours as traffic is divided in the two paths. Let's say the authorities build a bridge:

This will lead to a (weak) equilibrium of 2 hours as all agents take the route s-v-u-t.

This is called Braess's Paradox.

Side Note

We have actually seen this example occur almost verbatim in Seoul where the demolition of a bridge in 2005, solved a 2 decade old traffic problem.

Furthermore, Steinberg and Zangwill, 1983; showed that in a random network, Braess's paradox is approximately 50% likely to occur in an random network.

It is also a consideration in google maps where the navigation sometimes suggests a longer route, not to avoid a pre-existing traffic jam, but to avoid creating one. (This is why google map is not referentially transparent and may suggest two people different routes between same places at same time)

TODO.

1.2. Prisoner's Dilemma

$$\begin{array}{c|cccc} & \mathbf{P2} & & & \\ & C & D & \\ \mathbf{P1} & C & 4,4 & 5,1 \\ D & 1,5 & 2,2 & \end{array}$$

Here both players have incentive to deviate from the mutually best case as confessing (strongly) dominates denial and hence, is a Nash equilibrium.

Let's define these words formally.

Definition: Game

To define a game we need to know the players and strategies for each player. Thus, a game $G = (P, S, \mu)$ where for i in P, S_i in S denotes the set of possible strategies for player i.

In a particular play of the game denoted as s, i plays strategy s_i forming the strategy profile or game vector $(s_1, s_2, ..., s_n)$.

We denote the payoffs or costs of the game for player i using a function μ_i : $S_1 \times S_2 \times ... \times S_n \to \mathbb{R}$ which takes the game vector and tells the payoff for player i. $\mu: S_1 \times S_2 \times ... \times S_n \to \mathbb{R}^n$; $\mu(s) = (\mu_1(s), \mu_2(s), ..., \mu_n(s))$ is the payoff vector returning function.

Finally, for conciseness, we sometimes denote the choices for all players except i as s_{-i} . Thus, $\mu_i(s_i, s_{-i})$

Definition: Strongly Dominant Strategy

Player i's strategy $\hat{s_i}$ is a **Strongly Dominant Strategy** to the strategy s_{-i} of other players if:

$$\mu_i(\hat{s_i}, s_{-i}) > \mu_i(s_i', s_{-i}) \forall s_i' \in S_i$$

Definition: Weakly Dominant Strategy

Player i's strategy $\hat{s_i}$ is a **Weakly Dominant Strategy** to the strategy s_{-i} of other players if:

$$\mu_i(\hat{s_i}, s_{-i}) \ge \mu_i(s_i', s_{-i}) \forall s_i' \in S_i$$

and

$$\exists s_i' \in S_i \text{ s.t.} \mu_i(\hat{s_i}, s_{-i}) > \mu_i(s_i', s_{-i})$$

Definition: Weakly Dominant Strategy / Best Response(BR)

Player i's strategy $\hat{s_i}$ is a **best response** to the strategy s_{-i} of other players if:

$$\mu_i(\hat{s_i}, s_{-i}) \ge \mu_i(s_i', s_{-i}) \forall s_i' \in S_i$$

or if $\hat{s_i}$ solves $\max_{S_i} \mu_i(s_i, s_{-i}).^1$

Definition: Strongly Dominated Strategy Equilibrium

Informally, this is when all players are playing dominant strategies.

It is a strategy profile $(s_1^*, s_2^*, ..., s_N^*)$ is a SDSE if for each i, her choice s_i^* is strongly dominant to all .

Definition: Nash Equilibrium(NE)

Informally, this is when all players are playing BR to each other.

Formally, it is a strategy profile $(s_1^*, s_2^*, ..., s_N^*)$ is a NE if for each i, her choice s_i^* is a best response to s_{-i}^* .

¹Sometimes we can replace the actual strategies by others by p, which is i's belief of others' choices. This is often done in econ, but here, one of our assumptions (Common knowledge) allows us to not need it. The BR word is also from Econ.

Remark

The reason Nash equilibrium is important is as it leads to no-regrets as no individual can do strictly better by deviating holding others fixed. Second, as it is a self-fulfilling prophecy (we will see what this means).

1.3. Pollution Control

Let there be n countries with the cost of pollution control being 3. If a country doesn't control pollution, it adds cost 1 to each country.

This leads to the dark case of no one controlling pollution. We can check that if only k countries control pollution, all have incentive to not control.

Definition

A dominant strategy is what is best for a player regardless of whatever strategy the rest of the players choose to adopt.

1.4. RPS

There is no pure Nash equilibrium here. But allowing randomized strategy, we can get an equilibrium.

Definition: Mixed Strategy

A mixed strategy p_i is a randomization over i's pure strategies.

- $p_i(s_i)$ is the probability *i* assigns to the pure strategy s_i .
- $p_i(s_i)$ could be zero for some i.
- p_i could be one (in case of a pure strategy).

Definition: Mixed Strategy Profile

A mixed strategy profile is a tuple $(p_1, p_2, ..., p_n)$ where each p_i is a mixed strategy for player i. It represents the joint behavior of all players where each one plays a randomized strategy independently.

Definition: Expected Payoff

The expected payoff for player i is:

$$\sum_{(s_1,\ldots,s_n)\in S_1\times\ldots\times S_n} \mu_i(s_i,s_{-i}) \prod_{a=1}^n p_a(s_a)$$

Definition: Mixed Strategy Nash Equilibrium

A mixed strategy profile $(p_1^*, p_2^*, ..., p_n^*)$ is a mixed strategy NE (MSNE) if for each player i, p_i^* is a BR to p_{-i}^* . That is:

 $\mu_i(p_i^*, p_{-i}^*) \geq \mu_i(\sigma_i, \sigma_{-i}^*) \forall \sigma_i \in \text{probability distribution over } S_i$

Nash's Theorem 1.1. Every bimatrix game has a (pure or mixed) Nash equilibrium.

Theorem 1.2. For zero-sum games, it is polytime; otherwise, it is PPAD-hard.

PPAD-hard $\Rightarrow NP$ -Hard $\iff NP = co-NP$. This is open and unknown.

1.5. Sealed Bids Auctions

There is one seller and n buyers and one item that the seller wants to sell.

Buyers have non-negative valuations over this item v_i .

The rules of this auction are that each buyer submits a sealed bid b_i be the bid amounts. The highest bid gets the item (in case of ties, by the lower index).

If buyer i gets the item, and pays t_i , then their $\mu_i = v_i - t_i$ and payoff for other buyers is 0.

Definition: First Price Auctions

In first price auction, $t_i = b_i$.

Definition: Second Price Auction

Buyer who gets the items (say i) pays the second highest bid

Theorem 1.3. Second price auction is weakly revealing (that is it is a weakly dominant strategy to bid truthfully).

Proof. We will analyze for v_i and then see that the same holds with small changes. \blacksquare

1.6. Battle of the Sexes

Definition

We represent a situation where two agents must simultaneously take an action where each of them prefers one option over the other but prefer coordination over doing different things. And example occurrence would be²:

Wife

Husband

	Cricket	Music
Cricket	2,1	0,0
Music	0,0	1,2

We can try to brute force this. Let's look at the payoffs for both the players

$$\begin{split} \mu_1(\sigma_1,\sigma_2) &= \sigma_1(C)\sigma_2(C)\mu_i(C,C) + \\ &\sigma_1(C)\sigma_2(D)\mu_i(C,D) + \\ &\sigma_1(D)\sigma_2(C)\mu_i(D,C) + \\ &\sigma_1(D)\sigma_2(D)\mu_i(D,D) \\ &= 2\sigma_1(C)\sigma_2(C) + \sigma_1(D)\sigma_2(D) \\ &= 2\sigma_1(C)\sigma_2(C) + (1-\sigma_1(C))(1-\sigma_2(C)) \\ &= 3\sigma_1(C)\sigma_2(C) - \sigma_1(C) - \sigma_2(C) + 1 \end{split}$$

And similarly

$$\mu_2 = 3\sigma_1(C)\sigma_2(C) - 2\sigma_1(C) - 2\sigma_2(C) + 2$$

Using
$$\mu_1(\sigma_1^*, \sigma_2^*) \ge \mu_1(\sigma_1, \sigma_2^*) \forall \sigma_1 \in \Delta(S_1)$$

$$\sigma_1^*(C)[3\sigma_2(C)-1] \geq \sigma_1(1)[3\sigma_2(C)-1] \forall \sigma_1(c) \in (0,1)$$

Similarly

$$\sigma_2^*(C)[3\sigma_1(C)-2] \geq \sigma_2(1)[3\sigma_1(C)-2] \forall \sigma_2(c) \in (0,1)$$

If
$$3\sigma_2^*(C) - 1 > 0 \Rightarrow \langle (1,0), (0,1) \rangle$$
.

If
$$3\sigma_2^*(C) - 1 < 0 \Rightarrow \langle (0,1), (1,0) \rangle$$
.

If
$$3\sigma_2^*(C) - 1 = 0 \Rightarrow \langle \left(\frac{2}{3}, \frac{1}{3}\right), \left(\frac{1}{3}, \frac{2}{3}\right) \rangle$$
.

1.7. Properties of MSNE

Expected payoff for player i will be:

²Which is extremely stereotypical and doesn't represent the author and hopefully the prof's views.

$$\begin{split} \mu_i(p_1, p_2, ..., p_n) &= \sum_{(s_1, ..., s_n) \in S_1 \times ... \times S_n} \mu_i(s_i, s_{-i}) \prod_{a=1}^n p_a(s_a) \\ &= \sum_{s_i \in S_i} \sum_{s_{-i} \in S_{-i}} p_i(s_i) p_{-i}(s_{-i}) \mu_i(s_i, s_{-i}) \\ &= \sum_{s_i \in S_i} p_i(s_i) \sum_{s_{-i} \in S_{-i}} p_{-i}(s_{-i}) \mu_i(s_i, s_{-i}) \\ &= \sum_{s_i \in S_i} p_i(s_i) \mu_i(s_i, p_{-i}) \end{split}$$

This makes the utility of a player a convex combination of thier pure stratergy payoffs.

Definition: Convex Combination

A convex combination of $a_1,a_2,...,a_n$ is $\sum_{i=1}^n \lambda_i a_i$ where $\lambda_i \in [0,1]$ and $\sum_{i=1}^n \lambda_i = 1$.

An obvious observation is that convex combination of $a_1, ..., a_n \leq \max\{a_i\}$.

Which implies that the payoff with mixed stratergy is less than equal to max payoff with a pure strategy s_i . This implies:

$$\max_{\sigma_i \in \Delta(S_i)} \mu_i(\sigma_i, \sigma_{-i}) = \max_{s_i \in S_i} \mu_i(s_i, \sigma_{-i})$$

Theorem 1.4. $(\sigma_1^*,...,\sigma_n^*)$ is a MSNE if and only if $\forall i \in N$

- 1. $\mu_i(s_i, \sigma_{-i}^*)$ is the same for all $s_i \in support$ of σ_i^* .
- $2. \ \mu_i(s_i,\sigma_{-i}^*) \geq \mu_i(s_i^*,\sigma_{-i}^*) \forall s_i' \notin support \ of \ \sigma_i^*, s_i \in support \ of \ \sigma_i^*.$

Remark: Implications

Each player gets the same payoff for any pure strategy in the support of the MSNE strategy.

2. Equilibrium Computation

2.1. Computing a SDSE

Example

Notice, E is dominated by F as $\forall i, \mu_2(F, s_{-i}) > \mu_2(E, s_{-i})$. THis practically makes the game:

$$\begin{array}{c|cccc} & & P_2 \\ & D & F \\ & A & 4,3 & 6,2 \\ \hline P_1 & B & 2,1 & 3,6 \\ & C & 3,0 & 2,8 \\ \end{array}$$

Now A dominates B, C and after elimination, D will dominate E and we will be left with the nash equilibrium of 4, 3.

Also note, (A, D) is a PSNE.

Note, this algorithm by no means gives all the nash equilibrium, if there are multiple. We don't run into such issues with SDSE as only one can exist by the definition of Strict dominance.

Example

We can eliminate F as D, E are strictly better.

$$\begin{array}{c|cccc} & & P_2 \\ & D & E \\ & A & 3,1 & 0,1 \\ P_1 & B & 0,1 & 4,1 \\ & C & 1,1 & 1,1 \\ \end{array}$$

Here, we can eliminate C as if P_2 plays D or E, we are better off playing A or B respectively.

Another way to argue the same is $\mu_1\left(\frac{A+B}{2},s_{-i}\right)>\mu_1(C,s_{-i}).$

Side Note

Here, playing C is called the Bayesian Equilibrium as it is safe.

Example

We can get the gurentee finding the nash equilibrium by identifying the highest entry per row and column wrt the respective players.

Making (5,5) the PSNE.

Algorithm 2.1. For the column player, mark the maximum entry for them.

For the row player, mark the maximum entry for them.

The intersections are PSNEs.

2.2. Two Player Zero Sum Games

Definition: Two Player Zero Sum Games

A game with:

- $N = \{1, 2\}$
- $S = \{S_1, S_2\}$
- $\mu = \{\mu_1, \mu_2\}$
- $\bullet \ \mu_1(s_1,s_2) = -\mu_2(s_1,s_2)$

In these games, we only need to specify the payoffs for one player. We, by convention, do this for the row player.

B

$$\begin{array}{c|ccccc}
2 & 1 & 1 \\
-1 & 1 & 2 \\
\hline
1 & 0 & 1
\end{array}$$

For any stratergy, i of P_1 and P_2 will choose a stratergy such that,

- P_1 chooses $\max_i \min_j a_{ij}$ (maxmin)
- P_2 will choose $\min_j \max_i a_{ij}$. (minmax)

If maxmin and minmax are equal, we are done and the value is the nash equilibrium.

Definition: Maxmin-Minmax

The maxmin value refers to $\max_{i \in S_1} \min_{j \in S_2} a_{ij}$.

The minmax value refers to $\min_{j \in S_2} \max_{i \in S_1} a_{ij}$.

If a PSNE exists, we will get it by this process.

If there is no PSNE, this obviously doesn't work.

We can also discuss Saddle points.

Definition: Saddle Point

(i,j) is a saddle point of a matrix A if $a_{ij} \geq a_{kj} \forall k$ and $a_{ij} \leq a_{il} \forall l$

Theorem 2.2. If i, j and k, h are saddle points, then (i, h) and k, j are also saddle points.

Proof.

$$a_{ij} \ge a_{kj} \ge a_{kh} \ge a_{ih} \ge a_{ij}$$

And we are done by squeeze theorem.

Definition: Mixed Stratergy in 2 player zero sum game

Let $|S_1| = m$ and $|S_2| = m$. Let $x = (x_1, x_2, ..., x_n)$ be a mixed strategy for P_1 and $y = (y_1, y_2, ..., y_n)$ be a mixed strategy for P_2 .

The expected payoff is $\sum_{i=1}^n \sum_{j=1}^m x_i y_j a_{ij} = x^T A y$

We can define maxmin and minmax values here as:

Definition: Maxmin-minmax

 $\text{maxmin value} = \max_{x \in \Delta(S_1)} \min_{y \in \Delta(S_2)} x^T A y$

 $\operatorname{minmax value} = \operatorname{min}_{y \in \Delta(S_2)} \operatorname{max}_{x \in \Delta(S_1)} x^T A y$

Lemma 2.3.

$$\min_{y \in \Delta(S_2)} x^T A y = \min_{j \in S_2} \sum_{i=1}^m a_{ij} x_i$$

Proof. It is obvious that

$$\min_{y \in \Delta(S_2)} x^T A y \le \min_{j \in S_2} \sum_{i=1}^m a_{ij} x_i$$

as $S_2 \subseteq \Delta(S_2)$.

To do the other way round,

$$x^{T}Ay = \sum_{j=1}^{n} y_{j} \sum_{i=1}^{m} x_{j} a_{ij}$$

$$\geq \sum_{i=1}^{n} y_{j} \min_{k \in S_{2}} \sum_{i=1}^{m} x_{i} a_{ik}$$

$$= \min_{k \in S_{2}} \sum_{i=1}^{m} x_{I} a_{ik} \cdot \sum_{i=1}^{n} y_{j}$$

$$= \min_{k \in S_{2}} \sum_{i=1}^{m} x_{I} a_{ik}$$

Thus, by squeeze theorem, we are done.

2.3. Linear Programming for the win

We make an LP for the row player as:

The row player has to to maximize $\min_{j \in S_2} \sum_{i=1}^m a_{ij} x_i$ with the constrains $\sum_{i=1}^m x_i = 1, x_i \ge 0 \forall i \in \{1, 2, ..., m\}$.

Equivalently, maximize z with the constrains $z \leq \sum_{i=1}^m a_{ij} x_i \forall j \in \{1, 2, ..., n\}, \sum_{i=1}^n x_i = 1, x_i \geq 0 \forall i \in [m].$

Exercise: Column Player's LP

Define the column players LP.

Solution. minimize w such that $w \ge \sum_{j=1}^n a_{ij} y_j \forall i \in [m], \sum_{j=1}^n y_j = 1, y_j \ge 0$ for all $j \in [n]$.

2.3.1. Duel of LP

Example: Toy LP

 $\max 3x_1 + 2x_2 + x_3$ with constraints

- 1. $x_1 + x_2 + x_3 \le 2$
- $2. 3x_1 + x_3 \le 4$
- $3. \ x_1 + x_2 + x_3 \le 5$
- 4. $x_1, x_2, x_3 \ge 0$

We can get an upper bound by $3 * eq 3 \Rightarrow 3x_1 + 3x_2 + 3x_3 \le 15$.

We can get a better upperbound by eq $1 + \text{eq } 2 \Rightarrow 3x_1 + 3x_2 + 3x_3 \leq 9$.

The idea is that as at least one coefficient is bigger, the sum is bigger and is an upperbound.

But doing this for all combinations is going to be painfully time consuming. Let's try to do this algebraically and let the coefficients of equation 1,2,3 be y_1, y_2, y_3 in the linear combination.

$$x_1(y_1 + 3y_2 + y_3) + (y_1 + y_3)x_2 + (y_2 + y_3)x_3 \le 2y_1 + 4y_2 + 5y_3$$

This leads to a LP

Minimize $2y_1 + 4y_2 + 5y_3$ with the constraints:

- $y_1 + 3y_2 + y_3 \ge 3$
- $y_1 + y_3 \ge 2$
- $y_2 + y_3 \ge 1$

Theorem 2.4. The Row player LP and Column player LP are duel pairs.

Proof.

TODO. Computation

2.4. Strong Duality

Optimum value of f is the optimal value of its primal duel.

Ler $x^* = (x_1^*, x_2^*, x_3^*, ..., x_m^*), z^*$ be the optimum values for Row player.

 z^* must attain equality at some $j^* \in [n]$ that is $z^* = \sum_i a_{ij^*} x_i^*$ and $z^* \leq \sum_i a_{ij} x_i^* \forall j \in [n]$.

By lemma, $z^* = \min_{j \in S_2} \sum_{i=1}^n x_i^* = \min_{y \in \Delta(S_2)} x^{*^T} A y$ and similarly, $w^* = \max \sum_{j=1}^n a_{ij^*} y_i = \max_{x \in \Delta(S_2)} x^T A y^*$.

Thus,

Arjun Maneesh Agarwal

$$\min_{y \in \Delta(S_2)} {x^*}^T A y = \max_{y \in \Delta(S_2)} x^T A y^*$$

This is a nash equilibrium as no player can unilaterally increase payoff by moving.

2.5. Existence of Nash Equilibrium (mixed) in finite strategic form games

Ler $(N, \langle s_i \rangle, \langle \mu_i \rangle)$ be the game where $N = \{1, 2, ..., n\}$, S_i is stratergy set for player i, with $|S_i| = m \forall i$ and and $\mu_i : S_i \times S_{-i} \to \mathbb{R}$ is the payoff function for player i.

Mixed strategy σ_i is a probability distribution over S_i .

 Δ_i of $\Delta(S_i)$ denotes the set of all mixed stratergies for player i. $\Delta = \Delta_1 \times \Delta_2 \times ... \times \Delta_m$.

Expected payoff from δ_i for player i is

$$\mu_i(\sigma_i) \stackrel{\Delta}{=} \sum_{(s_1, \dots, s_n) \in S_1 \times S_2 \dots S_n} \Biggl(\prod_{j=1}^n \sigma_j \bigl(s_j\bigr) \Biggr) \mu_i(s_1, \dots, s_n)$$

Definition

 σ^* is a Nash Equilibrium if for every player i,

$$\mu_i(\sigma^*) \geq \mu_i(s_i, \sigma_{-i}^*) \forall s_i \in S_i$$

Brouwer's Fixed Point Theorem 2.5. Let B be a closed, bounded convex set. Let $f :: B \to B$ be a continuous function, then $\exists x \in B \text{ s.t. } f(x) = x$

We want to define B, f such that the Nash Equilibrium is the fixed point of f. Define $B = \Delta$.

Define f such that $\sigma \in \Delta$ is not a NE then $f(\sigma) \neq \sigma$ NS IF σ^* is a NE then $f(\sigma^*) = \sigma^*$.

Attempt 1: Define $f(\sigma) = \rho$ where $\rho \in \Delta, \rho = (\rho_1, \rho_2, ..., \rho_n)$ such that

$$\rho_i = \arg\max_{\delta_i \in \Delta_i} \mu_i(\sigma_{-i}, \delta_i)$$

Recall, this is called the best response.

The problem is, this is not a function and if we apply a tie breaking rule, it is not continuous. We could use the powerset as the domain, but that would require Katakumi's fixed point which is more analytical than we wish to be.

Example: Matching Pennies

Let row player choose the mixed strategy (p,1-p) and column player choose (q,1-q). The problem is

$$p > \frac{1}{2} \Rightarrow q = 0$$

$$p < \frac{1}{2} \Rightarrow q = 1$$

$$p = \frac{1}{2} \Rightarrow 0 \le q \le 1$$

This is an counter example to the continuity of f.

Modifying f: We first define a gain function of player i for deviation to s_{ij} from σ_i .

$$g_{ij} = \max \left\{ \mu_i \! \left(\sigma_{-i}, s_{ij} \right) - \mu_i (\sigma), 0 \right\}$$

We now define

$$f_{ij}\sigma = \frac{\sigma_{ij} + g_{ij}(\sigma)}{\sum_{k=1}^m (\sigma_{ik} + g_{ik}(\sigma))} = \frac{\sigma_{ij} + g_{ij}(\sigma)}{1 + \sum_{k=1}^m g_{ik}(\sigma)}$$

We want

$$\sum_{k=1}^m f_{ik}(\sigma) = 1$$

We will define

$$\begin{split} f(\sigma) &=:= \rho \\ f(\sigma) &= f(\sigma_{11},...,\sigma_{1m},...,\sigma_{n1},...\sigma_{nm}) \\ &= (\rho_1,...,\rho_{1m},...,\rho_{n1},...,\rho_{nm}). \end{split}$$

Let σ^* be a fixed point of f.

$$\begin{split} f_{ij} &= \sigma_{ij}^* \\ \sigma_{ij}^* &= \frac{\sigma_{ij} + g_{ij}(\sigma)}{1 + \sum_{k=1}^m g_{ik}(\sigma)} \\ \iff g_{ij}(\sigma^*) &= 0 \forall j \end{split}$$

TODO. Will complete from Solan...

Thus, by Brower's, we are done.

2.6. Two Player Non-Zero Sum Games

Definition

Given players 1, 2 and strategy sets S_1, S_2 and payoff matrices R for player 1 and C for player 2. A mixed strategy (x^*, y^*) is Nash Equilibrium if and only if

$$x^{*^T}Ry^* \ge (Ry^*)_i \forall i \in [n]$$
$$x^{*^T}Cy^* \ge \left(x^{*^T}R\right) \forall i \in [n]$$

where the LHS are expected payoffs. Also (M_i) is the i^{th} position in the matrix. We could also write this as $e_i^T R y^*$ and $x^{*^T} R e_i$ respectively.

Notice, if one switches say R for R' = R + a that is

$$\begin{bmatrix} r_{1,1} + a & \dots & r_{1,m} + a \\ r_{2,1} + a & \dots & r_{2,m} + a \\ \vdots & \vdots & \vdots \\ r_{n,1} + a & \dots & r_{n,m} + a \end{bmatrix}$$

Claim 2.6. Set of NE for (R', C) are same as that of (R, C). This implies, by symmetry, that (R, C + b) has same NEs as (R, C).

Claim 2.7. Set of NE remain unchanged for $(\frac{1}{a}R, C)$ wrt (R, C) and similarly the set of NE remains unchanged for $(R, \frac{1}{b}C)$ wrt (R, C).

This allows us to only deal with $R_{i,j}, C_{i,j} \in [0,1]$.

2.6.1. NE by Support enumeration

Let $S \subseteq [n], T \subseteq [m]$ be set of strategies in the support of a NE that is $x_i > 0 \quad \forall i \in S, \, y_i > 0 \quad \forall i \in T.$

We will write a LP for this, named LP[S,T].

$$\begin{cases} x_i \geq 0 & \forall i \in [n] \\ y_i \geq 0 & \forall i \in [n] \\ \sum_{i=1}^n x_i = 1 \\ \sum_{i=1}^m y_i = 1 \end{cases}$$
 NE Constraints
$$\begin{cases} (Ry)_i & \geq (Ry)_j & \forall i \in S, j \in [n] \\ (x^TC)_i \geq (X^TC)_j & \forall i \in T, j \in [m] \end{cases}$$

Claim 2.8. A solution to the LP say (x^*, y^*) is a NE.

Proof. If x^*, y^* is not a NE then one of the players has an incentive to deviate to another pure strategy, which violates the NE constraints

NE ALGORITHM BY SUPPORT ENUMERATION

- 1 for each $S \subseteq [n], T \subseteq [m]$:
- 2 | if LP[S,T] has a feasible solution (x, y)

This clearly has a $2^{n+m} \operatorname{poly}(n+m)$ running time.

This is clearly not polytime. As we shall see, that the solution lies in complexity class PPAD and is hence, believed not to be possible in polytime.

2.6.2. Lemke-Howson Algorithm

Characterization of NE for this algorithm is using the translation and scaling transforms and using the fact that the max achievable payoff is always 1 and the payoffs are ≥ 0 . We say $\left(\frac{x^*}{\sum^n x_i^*}, \frac{y^*}{\sum^m y_i^*}\right)$ is a NE if:

$$x_i^* = 0$$
 or $(Ry^*)_i = 1$ $\forall i \in [n]$

$$y_i^* = 0$$
 or $\left(x^{*^T}C\right)_i = 1$ $\forall i \in [m]$

The idea is that instead of the payoff's being variabales, we can sort of normalize them to 1 and then make a system of linear equations using it. This will

Definition: Polytope, Polyhedron, Half-Space, Vertex

A bounded **polyhedron** is **polytope**.

Intersection of half-spaces is called a polyhedron.

Given a n dimensional plane, the plane can be split into two parts by a n-1 dimensional hyper-plane. This is called **half-space**. For example ax + b > 0 defines a half-space in 2D while $a_1x_1 + a_2x_2 + a_3x_3 \ge 0$ defines a half-space in 3D.

Vertex/Extreme Points in \mathbb{R}^k is the intersections of k linearly independent hyper-planes.

Consider the polytope:

$$P = \left\{ (x,y) \mid x_i \underset{i \in [n]}{\geq} 0, y_i \underset{i \in [m]}{\geq} 0, (Ry)_i \leq 1, \left(x^TC\right)_i \leq 1 \right\}$$

We are assuming non-degeneracy here.

Definition: Non-Degeneracy

Any set of > m + n constraints do not meet at one point.

While the polytope itself doesn't define nash equilibria but some of it's vertex do. We will hop from vertex to vertex upto some condition to get nash equilibria.

At Nash equilibrium, by the stability condition, n of the equations in

$$\left\{x_i \underset{i \in [n]}{\geq} 0, (Ry)_i \leq 1\right\}$$

and m of the equations in

$$\bigg\{y_i \underset{i \in [m]}{\geq} 0, \big(x^TC\big)_i \leq 1 \bigg\}.$$

Thus, m + n many equalities the NE must have. That implies NE is a vertex of P.

The vertex $x, y = (\vec{0}_n, \vec{0}_n)$ is not a NE. This is called an artificial equilibrium.

A vertex x > 0 $Ry_i < 1$ but $x_2 = 0$, $R_2y = 1$, ... is not a NE. Stratergy 1 has +ve prov but not max payoff.

Let (\hat{x}, \hat{y}) be a vertex. Define a set of labels for each vertex. Define a set of labels for each vertex (\hat{x}, \hat{y}) has a label $i \in [n]$ if either $x_i = 0$ or $R_i y = 1$. Also (\hat{x}, \hat{y}) has a label n + j if $y_2 = 0$ or $x^T C^{(j)} = 1$.

Claim 2.9. (\tilde{x}, \tilde{y}) is a NE if and only if H has all m + n labels and $(\tilde{x}, \tilde{y}) \neq (\vec{0}_n, \vec{0}_m)$ Under the non-degeneracy assumption.

Goal To find $(\tilde{x}, \tilde{y}) \neq (\vec{0}_n, \vec{0}_m)$ and has all the labels.

So let's start at $(x_0y_0) = (\vec{0}_n, \vec{0}_m)$.

Fix label J, relax the constraint $x_1=0;\,x_2=\ldots=x_n=0,y_1=\ldots=y_n=0x_1>0.$

This new vertex, say (x_1, y_1) doesn't have label 1, but has a duplicate label $\in \{n + 1, ..., n + m\}$, say k = 1.

We relax the corresponding to the old duplicate label and proceed.

At any point, say t if (x_t, y_t) have all the labels, output it as a NE.

Claim 2.10. For any
$$i \neq j$$
, $(x_i, y_i) \neq (x_j, y_j)$

Proof. (x_t, y_t) has all labels and (x_0, y_0) is (0, 0).

All intermediate vertices (x_i, y_i) with duplicate labels k_i have only two neighbors, corresponding to the duplicates. With only two ways of coming, there are only two ways of going, ensuring that we can never repeat vertices.

Corollary 2.11. Every game has odd number of nash equilibrium.

Corollary 2.12. The odds in a mixed nash equilibrium are rational.

2.7. Mixed Nash Equilibriium in 2 Player Games

 $N = \{1, 2\}, S_1 = [n], S_2 = [m]$ with payoff matrices R, C.

Characterization of MNE is

$$P: \text{set of points } (x,y) \in \mathbb{R}^{m+n} \text{ s.t.}$$

$$x \geq 0 \forall i \in [n]$$

$$R_i y \leq 1 \forall i \in [n]$$

$$y_j \geq 0 \forall j \in [m]$$

$$x^T C_j \geq 0 \forall j \in [m]$$

 $(x,y) \in P$ is a MNE if and only if

$$\forall i \in [n], \text{either } x_i = 0 \text{ or } Ry_i = 1 : \text{Label } i \text{ cases}$$

$$\forall j \in [n], \text{either } x_j = 0 \text{ or } x^TC_j = 1 : \text{Label } n+j \text{ cases}$$

(x,y) has all labels in [m+n].

Non-Degeneracy assumption \Rightarrow exactly m + n labels for any vertex of P.

Note (0,0) has all labels but is not a NE.

Lemke-Hawson Algorithm

- Start at (0,0), fix label 1.
- 2 Relax the constraint \equiv label 1 (ie x = 0)
- 3 Goto next vertex $(x^{(1)}, y^{(1)})$
- 4 \perp Either all labels exist \Rightarrow MNE
- 5 Or a duplicate label k exists
- 7 Goto $(x^{(2)}, y^{(2)})$
- 8 so on...
- 9 Let $(x^{(0)}, y^{(0)}), ..., (x^{(t)}, y^{(t)})$ be the visited vertices.
- 10 All $(x^{(i)}, y^{(i)}), 0 < i < t$ miss label 1.

This algorithm is clearly exponential time as our polytope may have exponential vertices.

The edges we visit form a graph, specifically a path where the first and last vertex have degree 1 and the other vertices have degree 2.

2.8. Complexity of algorithm

As with most problems in computer science, we want to know how hard it is. After all after being saddened by not getting a polytime algorithm, we want to show it is unlikely that anyone else will³.

The problem in showing that it is NP lies in the definition of NP itself.

Definition: NP

NP is a class of decision problems with yes/no answer and there exists a polytime verifiable certicificate for a yes answer.

Our problem is not a decision problem. So what do we do?

Definition: Functional NP (FNP)

If there is a certificate (solution), output one.

Note, the certicificate should be polytime verifiable.

Clearly, MNE \in FNP. So can we show MNE is FNP-Complete.

Theorem 2.13. If MNE is FNP-Complete, NP = co-NP

Side Note

It is believed that NP \neq co-NP, not as strongly as P \neq NP but strongly enough. It is still open nonetheless.

Example

Take your favorite NP-complete problem. The instructor took Hamililtonian Path.

Let's there be a reduction from Hamililtonian Path to MNE.

Input will be a graph G in which we want to compute the Hamilitonian path.

Reduction will be something that takes a graph G and converts it into an instance of 2-Player Game Γ with the property:

G has a Hamililtonian path $\iff \Gamma$ has a MNE which maps back to "yes"

G has no Hamilitonian path $\iff \Gamma$ has a MNE which maps back to "no"

Let's take a slightly less ambitious goal.

Definition: TFNP

Total FNP is the class of FNP problems that always have a solution.

 $^{^3}$ Unless P = NP which is still unlikely.

This still doesn't help us out as there are no known TFNP problems.

So we go down to PPAD, a class contained in TFNP.

Definition: PPAD

Polynomial Parity Argument Directed version is a complexity class defined by a cannonical problem called the **end of line** problem.

Definition: End of Line

Given G possibly exponential sized graph with polytime algorithm (or circuit) to determine neighbours of a given vertex.

Every vertex has in-degree ≤ 1 and out-degree ≤ 1 .

Q: Given a source, find a sink (any sink, not the one corresponding to the source!)

Theorem 2.14. NME is PPAD complete

High Level Proof. NME is in PPAD by the Lemke-Hawson algorithm. We do this reduction in 2 steps.

- 1. Reduce End of Line to (approx) Brower's Fixed Point.
- 2. Reduce approx Brower Fixed Point to approx MNE.

We will do the first part by an intermediate step called **Sperner Lemma**.

Sperner's Lemma 2.15. Given a lattice as an input with the lattice points colored in three colors with every boundry being forbidden to use one color. The intermediate vertices can have any color (from the 3).

We define a triangle as 3 points in the same cell. That is a $1, 1, \sqrt{2}$ right angle triangle where lengths are unit.

Sperner's Lemma states that there exists a triangle with all vertices having distinct colors.

Definition: Sperner's Lemma Problem

Given a lattice as an input with the lattice points colored in three colors with every boundry being forbidden to use one color. The intermediate vertices can have any color (from the 3).

We define a triangle as 3 points in the same cell. That is a $1, 1, \sqrt{2}$ right angle triangle where lengths are unit.

Find: a triangle with all vertices having distinct colors.

We can solve Brower Fixed Point on $f:[0,1]^2\to [0,1]^2$, we want x s.t. f(x)=x.

We can just declare $0^{\circ} - 120^{\circ}$ as red, $120^{\circ} - 240^{\circ}$ as yellow and $240^{\circ} - 360^{\circ}$ as blue and color everything by this. We will use Sperner to find the approximate fixed point.

So our flow chart is

End of Line
$$\to$$
 Sperner Problem \to Approx Brower Fixed Point
 \to Arithmetic Circuit \to Game \to MNE
